

Towards Efficiency and Sparsity: Exploiting Personalized Terms for News Recommendation

Anonymous Author(s)

ABSTRACT

Some terms in a user's browsed news reveal her interests from the most fine-grained level. Capturing these **personalized terms** yields a highly compact and accurate user profile, significantly reducing the cost of using effective yet expensive matching models (e.g. BERT). The sparse terms bring interpretability to recommenders: the candidate generation process can be aligned to ad-hoc retrieval if we consider the personalized terms as query and the whole news set as document collection, where fast retrieval techniques can be employed. Due to lack of ground truth labels, we empower the model to learn to select representative terms, gaining a consistent improvement over heuristic selection baselines.

1 INTRODUCTION

2 RELATED WORK

In this section, we review the related work of news recommendation, feature selection and candidate recall.

2.1 News Recommendation

News recommendation has been widely explored for decades. Traditional collaborative filtering methods [5, 11] hash similar users into the same group by LSH before recommending. They either employ Matrix Factorization [9] to gather users. MF decomposes the user-item matrix to map users and items into the same latent space, where the inner product between their vectors captures the interaction score. Unlike movies or products, enormous news is spawn every second, outstripping the increase of users, which makes the user-item matrix especially sparse. Factorization Machine [13] then introduces real-valued features to MF to alleviate the sparsity, but it requires manual features which is time and labor demanding.

Content-based news recommendation then emerges to address the above issues. Early works of content-based methods still relies on some manual features such as topics [12], geographics [10], and demographics [4] to model news and users. In the recent ten years, deep learning shows an unlimited potential and prevails in the task of representation learning [3]. So more and more works are underway to design exquisite structures to learn representation of news and users directly from raw texts and browsing history respectively, taking the dot product between them as the click probability. Wu et al. [1, 15–20] proposes effective models that employs CNN, RNN, multi-head attention, and personalized attention to represent

news and users. External information such as knowledge [14] and user-item bipartite graph [8, 20] are also incorporated to enhance representations.

2.2 Efficient Transformers

More recently, large-scale pretrained language models (PLM in short) e.g. BERT [6] demonstrates impressive improvements over shallow and light-weighted neural models in NLP field. However, it is non-trivial to implement PLMs in the news recommendation scenario: the quadratic complexity of self-attention w.r.t. the input sequence length poses an intense challenge to speed up encoding users with dozens of historical articles that may contain thousands of words in total. Researchers make a lot of efforts to lessen this problem. SpeedyFeed [22] deduplicates user's historical news and candidate news in a batch, significantly speeding up the training process. Apart from optimizing training scheme in industry, more research modifies the self-attention layer to reduce complexity. For example, Longformer [2] sparsifies the full self-attention to a sliding and dilated pattern, which reduces the complexity to linear w.r.t. the input length; Fastformer achieves the same result by additive attention and element-wise production. It also achieves a new state-of-the-art performance on MIND [21], a large-scale dataset in news recommendation.

Another line of research follows a feature selection setting that prunes the input for expensive interaction. Hofstätter et al. [7] restricts BERT to only inspect top K important passages per document. It splits the selection and ranking stage, where the former is trained in teacher-student paradigm by the pseudo labels produced by a BERT, and the latter only scores the selected passages. However, cascading architecture requires labels for each stage, which is prohibitive in our scenario because there is no ground-truth indicating terms that the user really favors. Gallagher et al. [?] explores framework for jointly optimizing cascade search, but it is not practicable in a BERT-style model since it relies on specified empirical risk rather than ranking loss. The first application of sparse selection in news recommendation is SFI [?]. It sparsely and automatically selects important historical news for effective candidate-aware interaction, guaranteeing the efficiency and effectiveness of the model.

In our work, we select the browsing history at word-level to keep more fine-grained and comprehensive information instead of pruning the historical news set. With only a handful of personalized terms, we apply PLMs to promote the effectiveness of the recommender to a new level at competitive speed.
